ABSTRACT

Development of critical thinking instruments only focus on learning effectiveness, thus lacking the instrument measuring Critical Thinking Transfer Practice (CTTP) specific for medical undergraduates. This study aimed to develop an instrument that can measure CTTP amongst medical undergraduates in Malaysia with the primary focus on describing the steps for content validity calculation. A quantitative survey approach was applied through written questionnaire. Eight experts from public universities in Malaysia were selected through judgment sampling. The content validity calculation steps are presented in detail in form of Content Validity Index (CVI) and modified Kappa coefficient (K^*) values. The validity test involved 216 items, representing six sub-constructs. Item-level CVI (I-CVI), (K^*) scores and Scale-level CVI (S-CVI) were calculated for evaluation criteria, namely, Relevance, Clarity, and Representativeness of each item. Results revealed that 213 out of 216 items were rated as appropriate ($I-CVI \geq 0.80$) on all the evaluation criteria. From 213 items, 133 outstanding items were included in the instrument. After items deletion, the validity of the instrument improved. The study results may impact future development of critical thinking assessment in education. The instrument has the potential to be a CTTP psychometric measuring tool for medical undergraduates. The study will provides for others the knowledge of content validation process and procedures with emphasis on steps of content validity calculation. The study will also help medical educators to better understand CTTP sub-constructs. These sub-constructs may help them to create better critical thinking pedagogies.

INTRODUCTION

Critical thinking transfer is essential in students' learning especially when there is an educational transformation is required in learning the medical concepts. Nowadays, medical learning mainly focuses on analysis of the whole human body rather than subject-based learning approach (66). Educational transformation urges students to use knowledge and skills to analyze all medical concepts which helps them to comprehend information on human body. Apart from that, medical learning has changed from classroom learning to self-directed and blended learnings (65). This transformation urges medical undergraduates to transfer knowledge and skills that they have learnt from the classroom to new situations in order to survive in the real world.

Numerous studies have been conducted on critical thinking transfer (1–10). However, there were gaps in these studies. The first gap is that critical thinking transfer sub-constructs were not related to each other in reported theories (11–14). The second gap is that these sub-constructs were not specific to medical undergraduates' critical thinking learning. Besides, there is a lack of studies on instrument development that measures medical undergraduates' critical thinking transfer practice. Previous studies mainly focused on instruments that measure learning effectiveness by measuring the student's critical thinking skills and dispositions (15–21). Thus, this study aimed to develop an instrument that measures medical undergraduates' Critical Thinking Transfer Practice (CTTP). A separate CTTP instrument for medical undergraduates is needed because other established critical thinking instruments do not focus on critical thinking transfer that is important for medical undergraduates (16–19, 47–54).

Hence, this study created a Critical Thinking Transfer Practice (CTTP) instrument for medical undergraduates. The researchers came out with prior construct, process of critical thinking transfer practice for medical undergraduates, and six prior sub-constructs that represented construct based on the literature and theories (8, 11–12, 14, 55–65). The sub-constructs are: (A) Different conceptualizations on critical thinking transfer concepts, (B) Situations that allow critical thinking transfer, (C) Understanding and examining deep structure of the problem, (D) Rapid recognition of problem, (E) Deliberate practice, and (F) Learning strategies that promote critical thinking transfer. However, the prior construct and its sub-constructs were revised due to they were more relevant to non-medical context and connection between them have not been established. So, the final construct involved only medical undergraduates' Critical Thinking Transfer Practice (CTTP). Also, the six sub-constructs were amended to (A) Conceptualizing critical thinking transfer, (B) Determining situations that allow critical thinking transfer, (C) Understanding and examining deep structure of a problem, (D) Recognizing a problem rapidly, (E) Practising critical thinking deliberately, and (F) Determining strategies that promote critical thinking transfer.

The instrument was developed based on 10-phase development process. The phases were develop an initial thematic framework, conduct a qualitative study, fit the qualitative data into the initial thematic framework, develop the operational definitions, map the qualitative findings, confirm the qualitative findings, refine the qualitative data, develop the CTTP constructs and sub-constructs, develop the CTTP instrument, and instrument testing.

In developing the CTTP instrument, content validity is one of the crucial validations that must be conducted. It is often done via review of the literature, interview of relevant populations, and expert panel evaluation (22–25). It can also be achieved through three approaches, namely quantitative, qualitative, or mixed approaches (25–30). In the quantitative approach, the panel may use consistency and consensus strategies in evaluating the items (31–33). Metrics such as alpha coefficient, alpha consistency, kappa statistics, Content Validation Ratio (CVR), and Delphi are used to determine content validity scores for items in an instrument using mathematical calculations (28, 31–32, 34–35)

where different metrics have different calculation methods. Thus, a content validation calculation is defined as a calculation method of a content validity score using a quantitative metric.

The quantitative metric used in the study was the Content Validity Index (CVI) because it not only helps in making decisions on items (i.e., eliminating, modifying, or conserving them), but it is the most widely reported approach for content validity of an instrument (26, 28, 32, 36, 37). The CVI calculation is simple, easy to understand, and provides information about each item (28, 36). It also helps in evaluating the overall instrument through the calculation of Scale-level CVI (S-CVI). The CVI is much easier to interpret compared to the Content Validity Ratio (CVR). CVI determines items' status, whether the items are acceptable, needs revision or should be removed from the instrument.

Although content validation calculation is important, not many articles conduct this process (25–26, 29, 38). Therefore, the purpose of this study was to report the steps of content validity calculation. The content validation of the CTTTP instrument reported in the study is part of Phase 9 of the CTTTP instrument development. There were five steps involved in the content validation of this instrument. The steps were described in the method section, sub-section content validation steps.

METHODOLOGY

Critical Thinking Transfer Practice Instrument

The instrument was developed for measuring the level of medical undergraduates' Critical Thinking Transfer Practice (CTTP) in a public university in Malaysia. The researchers developed the instrument, construct (medical undergraduates' CTTP) and sub-constructs found in the literature (A - Conceptualizing the critical thinking learning transfer concept; B - Situations that allow critical thinking transfer; C - Understanding and examining deep structure of the problem; D - Rapid recognition of problem; E - Deliberate practice; F - Learning strategies that promote critical thinking transfer) in Malay language. Initially, the instrument contained 216 items for all the sub-constructs (A – 40 items; B – 28 items; C – 51 items; D – 33 items; E – 30 items; F – 34 items) as showed in the appendix. The English version of the instrument is attached in the appendix.

Content Validation Steps

Content validation of the CTTTP instrument reported in the study is part of Phase 9 of the CTTTP instrument development. A summary of the stages of content validation of the CTTTP instrument is reported in Phase 9. There were five stages involved in the content validation of this instrument.

Firstly, the aforementioned construct and six sub-constructs were conceptualized from the literature review.

Secondly, the researchers consolidated the previously reported construct and six sub-constructs found in the literature. This consolidation helped the researchers to understand the connection between the construct and sub-constructs.

In the 3rd stage, the existence of the six sub-constructs was confirmed through a qualitative study. This confirmation helped to ensure that the construct and six sub-constructs were contextual to medical undergraduates learning process.

An expert panel validated the six sub-constructs in the fourth stage, and the sub-constructs sufficiently represent the constructs (25, 29, 41). Thus, the expert panel evaluated the Representativeness of items in the instrument, Clarity of language and sentence structure of the items, and the Relevancy of the items as suggested by the literature (29, 42).

Finally, the items measuring the six sub-constructs were determined using CVI and K* values. K* value helped to determine the level of agreement for each item from outstanding (1.00), excellent (0.75–0.99), good (0.60–0.74), fair (0.40–0.59), or low (<0.40) (26, 31, 39).

Detailed Content Validation Calculation Steps

Content validation of the CTTP instrument was based on the the item – level content validation using Item-level Content Validity Index (I-CVI) and Modified Kappa coefficient (K*) calculations. Validation of the whole CTTP instrument is based on Scale-level Content Validity Index (S-CVI).

Item – Level Content Validation Calculation Step

CVI for each item (I-CVI) was calculated based on the total number of experts who gave three or four point for each rating criterion divided by the total number of experts (N = 8) as in formula (1).

$$I-CVI = \text{Total number of experts that give 3 or 4 point} / N \quad (1)$$

Calculation of I-CVI is important to decide whether to use or remove an item. This item decision was based on the Lynn's (32) range: >0.79 (Appropriate); 0.70-0.79 (Need Revision); <0.70 (Eliminated). The items within the "appropriate" range were retained and included in the CTTP instrument.

Besides deciding on an item, I-CVI was also converted to a K* value. This conversion helps in determining the level of agreement on the items. In deciding the K* score for each item, the researchers have calculated the probability of chance agreement (Pc) using formula number (2) (28).

$$Pc = [N! / (A!(N-A)!)] \times 5N(2)$$

As the study by Polit et al. (28) did not clearly show how this formula was applied, this current study explains in detail how the probability of chance agreement (Pc) is calculated. N refers to the total number of experts, i.e., eight (8) experts in this study. A is the total number of experts who gave 3 or 4 point for each evaluation criterion (Relevancy, Clarity, Representativeness). N! refers to the set of expert numbers. For example, if N=3, so N! (3!) = six because expert numbers 1, 2, and 3 can be arranged according to the following set of numbers: {123, 132, 213, 231, 312, 321}.

If the sum of N and A are the same, the number of experts who gave 3 or 4 point equals the total number of experts (N-A)! = 0!. Score 0! is one because an empty set {} can only be arranged with one probability of an expert set. Because the total number of experts in this study is eight, therefore, N! = 8! was calculated using the formula 8x7x6x5x4x3x2x1.

After determining the I-CVI and Pc scores, the K* score was calculated for each item for all evaluation criteria using the following formula, K* = (I-CVI-Pc)/(1-Pc). The K* score was interpreted based on the range adapted from the literature (31, 46). Items that were within the low range are usually eliminated (30).

Scale – Level Content Validation Calculation Step

Also, this study determined the Scale-level Content Validity (S-CVI), one of the vital step in determining the instrument validity. The definitions on the S-CVI from the literature (27, 37) brought the idea on steps of the S-CVI calculations namely S-CVI Universal Agreement (S-CVI / UA) or S-CVI Average (S-CVI / Ave). As the S-CVI / Ave is non-conservative and easy to interpret (26), thus, the researchers adapted the approach to calculate the S-CVI for the study instrument.

This study has described the content validity calculation aforementioned above by presenting the results based on the data analysis.

Methods Involved in the Calculation

Study Design

This study applied a quantitative survey approach using a written questionnaire, as it is more economical and faster, and ensured that all of the questionnaires could be collected (39–40). The survey was given to an expert panel face-to-face because technique is useful, as any issues regarding the use of survey can be resolved immediately (40).

Sampling

Eight experts from various public universities in Malaysia were selected. Based on the previous studies' suggestions (25, 30, 32, 43), this study used judgment sampling where the sample was chosen based on the subjects' expertise. Judgment sampling is the most appropriate method for this study because the expert panel can be chosen by the researchers based on a specific criteria. There were two types of experts in this study: professional experts and field experts (lay experts). The eight experts in this study consisted of five professional experts and three field experts.

Professional experts usually know the research field, have published on the issue, presented papers at national or international seminars, and have work experience and expertise to collaborate in the study (43–44). These experts help in identifying whether the instrument was well-developed for psychometric testing (44). In this study, the professional experts included experts who had expertise in critical thinking and instrument development. Other studies (43–44) supported this view, which stated that the selected professionals must be experts in the study area and in instrument development. At least one of the professional experts also need to be expert in linguistic area to evaluate the language used in each statement (45). Four professional experts were experts in critical thinking and instrument development, and one was a linguistic expert. The criteria used to select the professional experts were: (i) academic qualifications i.e. having a Doctorate in the field of expertise, (ii) at least five years of experience in the area, (iii) still working at the university, (iv) actively teaching or publishing in the related area, and (v) the expert's consent to engage and commit to this study.

The other three experts appointed were field experts that appointed consisted of individuals who were most related to the concept to be measured and selected based on their representativeness of the population of this study. The use of the research subject as an expert was parallel with the other studies (25, 43). Also, practitioners at the studied institution can become a source that allows the development and revision of the CTTP instrument due to their work and involvement with the actual population of the study (25). The literature suggests that a field expert is a non-professional who has devoted time and energy to acquire expertise. A field expert might also be defined as “non-professionals who hold some basic knowledge about a subject.” So, the field experts in this study may include dean, deputy dean, university program head, university instructors, or students. The field

expert group helps to evaluate item phrases, clarity of terms, and suggest essential and relevant items (43). The field experts in this study are the Deputy Head of a Clinical Department and a Clinical Lecturer in a public university in Malaysia. They have served in their roles for eleven and fifteen years, respectively. They are also currently active in teaching medical students in the institution. Also, another field expert included, a medical education expert from another public university in Malaysia.

Procedures

Experts' Invitations & Documents for Experts' Evaluation

The researchers met with the experts to explain the purpose and procedures of the study. Also, the purpose of the meeting is to gain the experts' permission to be involved in the study. The panel of experts was given two weeks to evaluate the instrument. However, the actual assessment time took between one month to two months.

Each expert was provided with the following:

- a. Information on the study, evaluation procedures, and criteria that these experts need to use.
- b. An expert's demographic survey form.
- c. An instrument evaluation form that contained detailed information about the objectives of the study, construct and sub-constructs to be measured, and operational definitions and measurement scales. In this evaluation form, a table containing the construct, sub-constructs, concepts to be measured, items and resources, and items for the evaluation criteria were attached.

Criteria for Content Validity of the Items

The criteria for the evaluation of the items were Relevancy (Rel), Clarity (Cla), and Representativeness (Rep). Each criterion was measured on a four-point Likert scale, as specified in Table 1. The Relevancy (Rel) criterion refers to the relationship between the items in this instrument to the construct and sub-constructs that the researchers want to measure. The Clarity (Cla) criterion refers to the clarity of the items in this instrument in terms of sentence structure, language, and type of words used. For the Representativeness (Rep) criterion, items were evaluated based on representativeness of the operational definitions.

Table 1: 4-point Likert scale in each evaluation criterion

Likert's scale	Evaluation criteria		
	Relevancy (Rel)	Clarity (Cla)	Representativeness (Rep)
1	Not relevant	Not clear	Not representative
2	Relevant but need major revision	Clear but need major revision	Representative but need major revision
3	Relevant but need minor revision	Clear but need minor revision	Representative but need minor revision
4	Very relevant	Very clear	Very representative

Data Analysis

Content validity analysis for this study was based on Item-level Content Validity described in the item selection section. Also, the whole instrument's evaluation based on the Scale-level Content Validity is described in the Determination of Instrument Content Validity section.

Item Selection

CVI and K^* scores were used as they provide more information on the items. For example, with I-CVI, the study only considers the items that fall within the “appropriate” ($I-CVI \geq 0.80$) range. The K^* score helps by filtering the “appropriate” items based on their level of agreement. Only items that were within the outstanding rating were considered in the CTTP instrument.

Determination of Instrument Content Validity

Next, content validity index for the scale level (S-CVI) was determined. This study adopted the following S-CVI definition, “the proportion of experts who score items as relevant or representative with either a 3 or 4”. (37, p.273). There are two S-CVI calculation methods, S-CVI Universal Agreement (SCVI/UA) and S-CVI Average (S-CVI/Ave). Of the two ways, S-CVI/Ave is found to be less conservative and more easily interpreted (31). The latter approach was used to calculate the S-CVI value for the instrument. The value is calculated by the sum of the overall values of the Content Validity Index for the items (I-CVI) divided by the total number of items in the instrument.

RESULTS

The key findings in this study are presented in terms of analysis of the Content Validity Index (CVI) and modified Kappa coefficient (K^*) values.

Number of Items in the First Draft of the CTTP Instrument

The first draft of the CTTP instrument comprised of 216 items with six (6) amended sub-constructs: (A) Conceptualizing of critical thinking transfer - 40 items, (B) Determining situations or cues that allow critical thinking transfer - 28 items, (C) Understanding and examining deep structure of problem - 51 items, (D) Recognizing a problem rapidly - 33 items, (E) Practicing critical thinking deliberately - 30 items, and (F) Developing strategies that promote critical thinking transfer - 34 items. These sub-constructs are listed in Tables 2 and 3.

The list of items together with the CVI and K^* scores of each item is attached in appendix. Selection of items for the CTTP instrument was based on the I-CVI and K^* values in appendix. As there were initially 216 items in the CTTP instrument, this study only considered the “appropriate” items ($I-CVI \geq 0.80$) and outstanding items ($K^* = 1.00$).

Table 2: The number of items based on the evaluation classification and I-CVI scores

Sub-constructs	Appropriate (>0.79)			Need Revision (0.70 - 0.79)			Eliminate (>0.70)			Total number of items
	Rel	Cl	Rep	Rel	Cl	Rep	Rel	Cl	Rep	
A	40	40	40	0	0	0	0	0	0	40
B	28	27	28	0	1	0	0	0	0	28
C	51	50	51	0	1	0	0	0	0	51
D	33	33	33	0	0	0	0	0	0	33
E	30	29	30	0	1	0	0	0	0	30
F	34	34	34	0	0	0	0	0	0	34
Total	216	213	216	0	3	0	0	0	0	216

Note: Rel = Relevancy; Cl = Clarity; Rep = Representative

Table 3: The number of items based on the evaluation classification and K* values

Sub-constructs	Outstanding (1.00)			Excellent (0.75 - 0.99)			Good (0.60 - 0.74)			Fair (0.40 - 0.59)			Poor (<0.40)		
	Rel	Cl	Rep	Rel	Cl	Rep	Rel	Cl	Rep	Rel	Cl	Rep	Rel	Cl	Rep
First evaluation															
A	38	36	38	2	4	2	0	0	0	0	0	0	0	0	0
B	20	19	21	8	8	7	0	1	0	0	0	0	0	0	0

E	21	21	21	0	0	0	0	0	0	0	0	0	0	0	0
F	25	25	25	0	0	0	0	0	0	0	0	0	0	0	0
Total	133	133	133	0	0	0	0	0	0	0	0	0	0	0	0

Note: Rel = Relevancy; Cl = Clarity; Rep = Representative

Item Status Based on Item-level Content Validity Index (I-CVI)

Table 2 in appendix shows the evaluation classification and I-CVI score based on guidelines from previous studies (25, 37, 45). Based on these guidelines, there were 216 items for the Relevancy criteria, 213 items for Clarity, and 216 items for Representativeness within the range from 0.80 to 1.00 which are classified as appropriate ($I-CVI \geq 0.80$) to be incorporated in the CTTTP instrument. Only three (3) items under the Clarity criterion ranged from 0.70 to 0.79, which would need further revision, and no item was below 0.70. These three (3) Clarity items would have to be revised but based on the suggestion by the literature (37, 45), these items were unacceptable ($I-CVI < 0.8$) for the new instrument. Hence, these items were eliminated from the CTTTP instrument, resulting in the CTTTP instrument draft comprising of 213 items.

Item Status based on the K* Value

The items in appendix were then evaluated using the K* value. Based on the results in Table 3, 177 items for Relevancy (Rel), 134 items for Clarity (Cla), and 176 items for Representativeness (Rep) were rated as outstanding. The excellent items for Relevancy (Rel), Clarity (Cla), and Representativeness (Rep) criteria were 39, 79, and 40 items, respectively. Three (3) other items were rated as good ($K = 0.72$) although their I-CVI was < 0.80 . Thus, the authors recommended that those three (3) items be eliminated. In the final part of the study, the researchers only considered the outstanding items ($K = 1.00$) in all the evaluation criteria. Based on the second evaluation using K* value, only 133 items out of 216 items in Table 3 have been addressed by the content experts as outstanding items based on all the evaluation criteria (Relevance, Clarity, and Representativeness). So, these 133 items were considered to be incorporated in the CTTTP instrument.

Scale-level Content Validity Index (S-CVI) of the CTTTP Instrument

Table 4 shows the calculation of content validity for the CTTTP instrument through SCVI/Ave. S-CVI/Ave score higher than 0.90 for an instrument is considered adequate content validity (31). Only 133 items with $S-CVI/Ave = 1.00$ were considered for inclusion in the CTTTP instrument from the analysis. So, it is anticipated that the CTTTP instrument has perfect Scale-level Content Validity.

Table 4: The calculation of S-CVI/Ave

	Relevancy			Clarity			Representativeness		
	>0.79	0.70-0.79	<0.70	>0.79	0.70-0.79	<0.70	>0.79	0.70-0.79	<0.70
No. of item	133	0	0	133	0	0	133	0	0
I-CVI Score	133	0	0	133	0	0	133	0	0
S-CVI	1.000			1.000			1.000		

Note: I-CVI = Item-level Content Validity Index; S-CVI = Scale-level Content Validity

DISCUSSION

This study has developed an instrument to assess medical undergraduates' Critical Thinking Transfer Practice (CTTP). In developing the instrument, the researchers have looked into established critical thinking instruments as the benchmark. In studies outside of Malaysia, the established critical thinking instruments focused on generally assessing the critical thinking ability of undergraduates. Some of the instruments focused on the critical thinking disposition constructs such as the California Critical Thinking Disposition Inventory (47), California Measure Mental Motivation (CM3) (48), EMI scale (17), and Yoons's Critical Thinking Disposition Instrument (18). Other established instruments focused on assessing the critical thinking skills of undergraduates, for example, Critical Thinking Appraisal Watson-Glaser (49), Ennis-Weir Critical Thinking Essay Test (50), California Critical Thinking Skills Test (51), Halpern Critical Thinking Assessment (16), Critical Thinking Collegiate Learning Assessment (52), and Cornell Critical Thinking Test (53). In Malaysia, the critical thinking instruments developed assessed on both dispositions and critical thinking proficiency of undergraduates such as Malaysia Critical Thinking Instrument (19) and "Instrumen Kemahiran Pemikiran Kritikal" (54). The established instruments have limited focus on the construct of critical thinking transfer. Thus, this study focused on the construct of Critical Thinking Transfer Practice (CTTP).

In focusing on the CTTP, the researchers found a prior construct namely the process of critical thinking transfer practice of undergraduates based on several underlying theories (11, 12, 14, 55–57). The researchers also came out with the six prior sub-constructs that represented the construct based on the literature (8, 58–65). The sub-constructs were: (A) Different conceptualizations on critical thinking transfer concepts, (B) Situations that allow critical thinking transfer, (C) Understanding and examining deep structure of the problem, (D) Rapid recognition of problem, (E) Deliberate practice, and (F) Learning strategies that promote critical thinking transfer. However, the construct and sub-constructs were primarily relevant for general learning context and the relationship between construct and sub-construct has never been established. Thus, the researchers conceptualized the construct and sub-constructs relevant to medical undergraduates learning context based on the combination of theories, past studies and a qualitative study. Based on researchers' conceptualization, the study has given added value to the current knowledge regarding the relationship between the CTTP construct and sub-constructs. The prior construct was revised to make it more relevant to medical undergraduates' learning process. The final construct was the medical undergraduates' Critical Thinking Transfer Practice (CTTP). Also, the six sub-constructs amended to (A) Conceptualizing of critical thinking transfer, (B) Determining situations or cues that allow critical thinking transfer, (C) Understanding and examining the deep structure of problem, (D) Recognizing a problem rapidly, (E)

Practicing critical thinking deliberately, and (F) Developing strategies that promote critical thinking transfer.

Based on the CTTTP construct and sub-constructs, the study has contributed to advancing the current knowledge in critical thinking and instrument development area. Established instruments in the literature have limited focus on the Critical Thinking Transfer Practice (CTTP) construct. Thus, the study has developed an instrument that enables the assessment of CTTP construct based on the establishment of CTTP construct among learners. This instrument is significant for teachers and learners because it can be used to assess CTTP level among medical undergraduates. The assessment may help learners to improve their critical thinking transfer practice. Also, teachers may improve their teaching and learning strategies in the area of critical thinking via results from this instrument.

Previous studies did not test the representativeness of the sub-constructs towards the construct. The testing is important to confirm content validity of the construct to be measured. Therefore, this study has contributed to the literature by testing the representativeness of the CTTP sub-constructs towards the construct through content validation process. Content validity of the CTTP instrument was developed based on three steps: literature review, qualitative findings, and evaluation of the expert panel as suggested by previous researchers (25, 28–29, 32, 38, 66–69).

This study presented several advantages of using content validity steps. In the expert panel evaluation, the content validity was helpful to assess the items in the instrument. The decision on whether to eliminate, modify, or conserve the items was made using quantitative, qualitative and mixed approaches as suggested by previous researchers (25, 70–71). The first strength is that this paper discussed the determination of the CTTP instrument's content validity. The validity is determined through expert panel evaluation using a quantitative approach. It is based on the experts' evaluation of an item - the experts' consistency estimates or their consensus on the rating scale for item relevance (32–33, 36). This study utilized the consensus approach instead of consistency approach because the latter has many disadvantages in item evaluation. Secondly, even there are numerous numbers of metrics used for the item evaluation in the consensus approach, such as alpha consistency, kappa statistics, Content Validation Ratio, and Delphi (28, 31–32, 34, 71), however, the study used Content Validity Index (CVI) because it is easy to compute, interpret, and present in terms of item and instrument level analysis. The third strength was that this study has added value to previous studies by presenting the details of CVI calculations based on number of experts and converting CVI value to a Modified Kappa Coefficient (K^*) value. Previous studies (25–26, 31) did not show in detail on CVI calculation process. Fourth, this study has added value to the previous studies in which it applied three evaluation criteria (relevancy, clarity, and representativeness) in evaluating the items. The criteria may give more data in evaluating the instrument validity as compared to other studies (25–26) which included only two evaluation criteria. Fifth, this study has evaluated both Item-Level Content Validity and Scale-Level Content Validity as compared to other studies. Other studies adapted either item level, or instrument level evaluations (25–28, 30, 36, 72).

A possible drawback of this study is that the CVI index does not consider the possibility of inflated values because of chance agreement (26, 36). Chance agreement refers to a concern in evaluating inter-rater agreement indices, especially when the choices are dichotomous, as is the case when 4-point ratings are collapsed into the two categories of relevant and not relevant (28). Hence the modified Kappa coefficient (K^*) provides additional CVI information as it does not adjust for chance agreement (36). The K^* value helps in quantifying the level of agreement between experts (36).

CONCLUSION

In conclusion, CVI was used to determine the appropriate items to be included in the instrument. Then the K^* value was used to filter the items based on a defined level of performance. Items categorized as outstanding (I-CVI scored 1.00) were considered to be included in the instrument. The findings showed that the six sub-constructs could potentially be used to measure Critical Thinking Transfer Practice (CTTP) among medical undergraduates in Malaysia. In summary, the CTTP instrument with six sub-constructs and 133 items is ready to be performed to medical undergraduates. The study will benefit medical educators in understanding the CTTP sub-constructs in which these sub-constructs will help them create better critical thinking pedagogies. Also, the study provided specific content validation process and procedures that can be referred to and applied by other researchers. An added value offered by the study is that it emphasized the method of CVI calculation based on expert panel evaluation.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge the support from Faculty of Medicine, Universiti Kebangsaan Malaysia, and all the study experts. The authors also want to thank Associate Professor Ray Peterson from The University of Adelaide for his contribution and feedback on this manuscript. This work was supported by the “Sekretariat Penyelidikan Perubatan dan Inovasi”, Universiti Kebangsaan Malaysia Medical Centre under Grant FF-2017-436.
